A FINITE VOLUME ELEMENT SOLUTION BASED ON POSTPROCESSING TECHNIQUE OVER ARBITRARY CONVEX POLYGONAL MESHES

YANLONG ZHANG AND YANHUI ZHOU*

Abstract. A special finite volume element method based on postprocessing technique is proposed to solve the anisotropic diffusion problem on arbitrary convex polygonal meshes. The shape function of polygonal finite element method is constructed by Wachspress generalized barycentric coordinate, and by adding some element-wise bubble functions to the finite element solution, we get a new finite volume element solution that satisfies the local conservation law on a certain dual mesh. The postprocessing algorithm only needs to solve a local linear algebraic system on each primary cell, so that it is easy to implement. More interesting is that, a general construction of the bubble functions is introduced on each polygonal cell, which enables us to prove the existence and uniqueness of the post-processed solution on arbitrary convex polygonal meshes with full anisotropic diffusion tensor. The optimal $H^1$ and $L^2$ error estimates of the post-processed solution are also obtained. Finally, the local conservation property and convergence of the new polygonal finite volume element solution are verified by numerical experiments.

Key words. Finite volume element solution, postprocessing technique, convex polygonal meshes, existence and uniqueness, $H^1$ and $L^2$ error estimates.

1. Introduction

Finite volume method (FVM) is a popular and practical numerical method for solving partial differential equations, and it is widely used in computational fluid dynamics, computational heat transfer and other fields. The local conservation is an important property of FVM, and it is desirable in multiphase flow in porous media, energy conservation in thermodynamics and many other problems. Finite volume element method (FVEM) is usually regarded as a special type of FVM, where the solution space is the same as the classical finite element method. The mathematical development of FVEM can be found in [18, 20, 37]. For the two dimensional diffusion problems, most existing works of FVEM are only concentrated on triangular meshes (e.g. [1, 5, 6, 7, 9, 34, 36, 39]) or quadrilateral meshes (e.g. [14, 15, 19, 21, 23, 28, 38]). Polygonal meshes offer greater flexibility in mesh generation, merging and refinement, and they have been applied in many fields, such as computational fluid dynamics, topology optimization, analysis of fractured materials and crack propagation and so on. Thus, the construction of FVEM on polygonal meshes is an interesting and important research topic. Recently, [42] proposed a finite volume element method to solve the anisotropic diffusion equation on general convex polygonal meshes, and under the coercivity assumption, the authors proved the optimal $H^1$ error estimate. To our knowledge, the theoretical analysis of FVEM on arbitrary convex polygonal meshes still lags far behind. For instance, even though for the classical isoparametric bilinear FVEM, the corresponding coercivity result and optimal $L^2$ error analysis have not been established on arbitrary trapezoidal meshes.

*Corresponding author.
As we all know, since the bilinear form of classical finite element method (FEM) is symmetry, the coercivity result can be easily obtained (e.g. [2, 3]). Once the optimal interpolation error estimate is established, the optimal error analysis (e.g. $H^1$ and $L^2$) of FEM can also be proved by some standard techniques (e.g. Aubin-Nitsche). In recent decades, based on various generalized barycentric coordinates, some researchers extend the classical FEM to polygonal meshes, where the generalized barycentric coordinates are studied in [10, 11, 12, 16, 25, 33] for incomplete references. In [30], the polygonal FEMs based on Wachspress, mean value or Laplace generalized barycentric coordinates were developed. For more studies and applications about polygonal finite element method, the readers are referred to [24, 26, 29, 32, 35] and so on. At the same time, [13] (resp. [27]) studied the interpolation error estimates of triangulation, harmonic, Wachspress and Sibson (resp. mean value) coordinates, which is crucial to the optimal error estimates in polygonal FEM and FVEM.

Regrettably, the aforementioned polygonal FEM doesn’t satisfy the local conservation property in general. Thus, some researchers try to postprocess the FEM solution to obtain a new FVEM solution with the local conservation property. By postprocessing the continuous Galerkin finite element solution, [43] presented a high order finite volume element solution for the elliptic problem on triangular and quasi-parallelogram meshes, which has the local conservation property and preserves the $H^1$ and $L^2$ error estimates. Later, [40] generalized the theoretical results in [43] to the anisotropic diffusion equation on arbitrary trapezoidal meshes. Recently, by introducing some new bubble functions, [41] improved the postprocess technique in [43, 40], such that the new theoretical findings cover arbitrary triangular and convex quadrilateral meshes for the anisotropic diffusion equation with any full diffusion tensor. In addition, there are many other research results for the local conservative method based on FEM, e.g. [4, 8, 17, 22, 31].

Compared with the previous works, this article has several contributions. Firstly, by introducing a unified construction of bubble functions, we establish the existence and uniqueness, optimal $H^1$ and $L^2$ error estimates of the post-processed solution for the anisotropic diffusion equation on arbitrary convex polygonal meshes. Secondly, we note that the coercivity result in [42] does not cover general convex polygonal meshes, and the $L^2$ error estimate of it has not been established. Different from [42], here we present another routine to obtain a new polygonal finite volume element solution for solving the anisotropic diffusion equation, and the stability and convergence are verified on arbitrary convex polygonal meshes.

The rest of this article is organized as follows. In Section 2, we define some notations and introduce the polygonal finite element method based on Wachspress generalized barycentric coordinate. By postprocessing the polygonal finite element solution, in Section 3 we reach a polygonal finite volume element solution, and the local conservation, existence and uniqueness of the post-processed solution are verified in Section 4. The optimal error estimates in $H^1$ and $L^2$ norms are proved in Section 5. In Section 6, we present some numerical results to validate the accuracy, local conservation property and mesh flexibility of the proposed method. Some conclusions are given in the last section.

2. A polygonal finite element method

Consider the following anisotropic diffusion problem

\begin{align}
    -\nabla \cdot (\Lambda \nabla u) &= f \quad \text{in } \Omega, \\
    u &= g \quad \text{on } \partial \Omega,
\end{align}
where Ω is an open bounded polygonal domain in $\mathbb{R}^2$, and $f \in L^2(\Omega)$ is the source term. Here $\Lambda$ is a symmetric and positive definite matrix,

$$\Lambda \|v\|^2 \leq v^T \Lambda v \leq \overline{\Lambda} \|v\|^2, \quad \forall \ v \in \mathbb{R}^2,$$

where $\Lambda$, $\overline{\Lambda}$ are two positive constants, and $\| \cdot \|$ is the Euclidean norm. For simplicity of the proof, we assume the Dirichlet boundary condition $g = 0$ in the theoretical analysis.

2.1. The primary mesh and Wachspress shape function. In order to introduce the primary mesh, we firstly present the following notations and assumptions.

- $\mathcal{M}$, the set of disjoint polygonal cells, satisfying $\Omega = \bigcup_{K \in \mathcal{M}} K$. $K$, a generic cell in $\mathcal{M}$, is an open and connected subset of $\Omega$. Throughout, we suppose that $K$ is strictly convex in the sense that all interior angles of $K$ are less than $\pi$. $x_K$, $h_K$ and $\rho_K$ denote the position vector of the cell center, the diameter of $K$ and the radius of the largest circle inscribed in $K$ respectively, and $h = \max_{K \in \mathcal{M}} h_K$.
- $\mathcal{E}$, the set of disjoint edges. $\sigma$, a generic edge of $\mathcal{E}$, is an open line segment.
- $\mathcal{V}$, the set of vertices. $\nu$, a generic vertex of $\mathcal{V}$, is a vertex of the cell $K \in \mathcal{M}$. We also use the same notation $\nu$ to denote the position vector of the vertex $\nu$, and let $\nu^{int} = \mathcal{V} \cap \Omega$ be the interior vertices of $\Omega$.

Based on the above notations, the primary mesh $\mathcal{T}_h$ of $\Omega$ is defined by the triplet $(\mathcal{M}, \mathcal{E}, \mathcal{V})$. In this paper, we suppose that the primary mesh is conforming in the sense that the intersection of the enclosures of any two cells in $\mathcal{M}$ is either empty or a common vertex or a common edge.

Next, we begin to construct the Wachspress shape functions on a single polygonal cell $K \in \mathcal{M}$. Assume that $\nu_i$ ($i = 1, \cdots, n_K$) are the $n_K$ vertices of $K$, see Figure 1, where the vertices are arranged by anticlockwise. In the following discussion, if there is no ambiguity, we will drop the subscript $K$ in $n_K$ for simplicity of exposition.

For any $x \in \overline{K}$, let $A_i(x)$ be the area of the triangle with vertices $x$, $\nu_i$ and $\nu_{i+1}$, namely

$$A_i(x) = \frac{1}{2} (\nu_{i+1} - \nu_i)^T \mathcal{R} (x - \nu_i), \quad \forall x \in \overline{K},$$

where

$$\mathcal{R} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$
Here and hereafter, without special mention, the subscripts such as \(i\) and \(j\) related to the vertices of \(K\) will be understood as periodic ones with period \(n\) such that \(\nu_0 = \nu_n\), \(\nu_{n+1} = \nu_1\). It is easy to verify that \(A_i(x)\) is a linear scalar function with respect to \(x\). Moreover, we suppose that \(w_i(x)\) is the so-called weight function associated with \(\nu_i\). In particular, the following weight functions are proposed by Wachspress [33]

\[
w_i(x) = A_i(\nu_{i-1}) \prod_{j \neq i-1, i} A_j(x), \quad i = 1, \ldots, n,
\]

which are the polynomials of degree not greater than \(n - 2\) with respect to \(x\). Then, the Wachspress shape function associated with \(\nu_i\) on \(K\) is defined by

\[
\phi_i(x) = \frac{w_i(x)}{\sum_{j=1}^{n} w_j(x)}, \quad x \in K.
\]

The properties of Wachspress shape functions are similar to the classical nodal basis functions of Lagrange type on triangular or quadrilateral cells, here we list some of them.

**Proposition 1.** ([12, 25]) Assume that \(K\) is a strictly convex polygon. Let the weight function \(w_i(x)\) and shape function \(\phi_i(x)\) be defined by (5) and (6), respectively. Then, we have

\[
\phi_i(x) \in C^\infty(K), \quad 1 \leq i \leq n,
\]

\[
\phi_i(x) > 0, \quad 1 \leq i \leq n, \quad \forall x \in K,
\]

\[
\sum_{i=1}^{n} \phi_i(x) = 1, \quad \forall x \in K,
\]

\[
\sum_{i=1}^{n} \phi_i(x) \nu_i = x, \quad \forall x \in K.
\]

Moreover, \(\phi_i(x)\) has a unique continuous extension to \(\partial K\), satisfying (7), (8) and \(\phi_i(x) \geq 0\) for all \(x \in \overline{K}\), and it is linear on each edge of \(K\), satisfying the Lagrange property \(\phi_i(\nu_j) = \delta_{ij}, \quad 1 \leq i, j \leq n\), where \(\delta_{ij}\) denotes the Kronecker delta.

**Proposition 2.** ([12, 13]) The Wachspress shape functions on convex polygons have the invariance property: if the transformation \(T: \mathbb{R}^2 \to \mathbb{R}^2\) is a translation, rotation, reflection, uniform scaling, or combination of these, then \(\phi_i(x) = \phi_i(T(x))\), where \(\tilde{K} = T(K)\) and \(\tilde{\phi}_i\) is the Wachspress shape function defined on \(\tilde{K}\).

Once the Wachspress shape functions \(\phi_i (i = 1, \ldots, n)\) are well defined in each cell \(K\), then by a way similar to the construction of the classical \(P_1\) (resp. \(Q_1\)) nodal basis functions of Lagrange type on triangular (resp. quadrilateral) meshes, we can extend \(\phi_i\) to the whole domain \(\overline{\Omega}\). In particular, let \(\phi_\nu(x), x \in \overline{\Omega}\) be the Wachspress shape function associated with the vertex \(\nu \in \mathcal{V}\), then for any vertex \(\nu' \in \mathcal{V}\), we have

\[
\phi_\nu(\nu') = \begin{cases} 
1, & \text{if } \nu' = \nu, \\
0, & \text{if } \nu' \neq \nu.
\end{cases}
\]

Obviously, we have \(\phi_\nu \in C(\overline{\Omega})\).
2.2. A finite element method on polygonal meshes. With respect to the primary mesh \( T_h \), the finite element space for (1) and (2) is defined by

\[
U_h = \text{Span}\{\phi_\nu : \nu \in \mathcal{V}^{\text{int}}\}.
\]

It is easy to verify that \( U_h \subset H^1_0(\Omega) \). Moreover, there holds

\[
u = \sum_{\nu \in \mathcal{V}^{\text{int}}} u_h(\nu)\phi_\nu, \quad \forall u_h \in U_h.
\]

The polygonal finite element method for solving (1) and (2) is to find \( u_h \in U_h \), such that

\[
a(u_h, v_h) = (f, v_h), \quad \forall v_h \in U_h,
\]

where

\[
a(u_h, v_h) = \int_\Omega (\Lambda \nabla u_h) \cdot \nabla v_h \, dx \, dy, \quad (f, v_h) = \int_\Omega fv_h \, dx \, dy.
\]

Let the semi-norm and norm of Sobolev space \( H^m(D) \) be denoted as \( |\cdot|_m, D \) and \( \| \cdot \|_m, D \), and when \( D = \Omega \) we omit the subscript \( \Omega \). By (3), we find that

\[
a(u_h, u_h) \geq \lambda |u_h|^2_1, \quad \forall u_h \in U_h.
\]

Thus, the coercivity result of polygonal finite element bilinear form \( a(\cdot, \cdot) \) is verified by noticing (10), and then the existence and uniqueness of (9) can be obtained immediately.

Let the interior angle at the vertex \( \nu_i \) be denoted as \( \alpha_i \), i.e., \( \alpha_i = \angle \nu_{i-1}\nu_i\nu_{i+1} \).

Then, we introduce the geometric assumptions below.

- (G1) There exists a positive constant \( \gamma^* \) such that

\[
\frac{h_K}{\rho_K} < \gamma^*, \quad \forall K \in \mathcal{M}.
\]

- (G2) There exists a positive constant \( d_* \) such that

\[
\frac{1}{h_K} \min_{i \neq j} ||\nu_i - \nu_j|| > d_*, \quad \forall K \in \mathcal{M}.
\]

- (G3) There exists a positive constant \( \alpha^* \) such that

\[
\max_{1 \leq i \leq n} \alpha_i < \alpha^* < \pi, \quad \forall K \in \mathcal{M}.
\]

- (G4) There exists a positive constant \( \alpha_* \) such that

\[
\min_{1 \leq i \leq n} \alpha_i > \alpha_*, \quad \forall K \in \mathcal{M}.
\]

- (G5) There exists a positive constant \( n^* \) such that \( n < n^* \).

**Proposition 3** (Proposition 4 in [42], Proposition 4 in [13]). For the geometric assumptions (G1)-(G5), we have the following results:

1. (G2) and (G3) imply (G1); 2. (G1) implies (G4); 3. (G2) or (G3) implies (G5).

Proposition 3 implies that (G2) and (G3) are basic ones. Moreover, based on the two assumptions (G2) and (G3), we have the following interpolation error estimates. Next, we use \( A \lesssim B \) (resp. \( A \gtrsim B \)) to denote \( A \leq CB \) (resp. \( A \geq CB \)), where \( C \) is a positive constant and independent of \( K \) and \( h \). Moreover, \( A \sim B \) denotes that we have both \( A \lesssim B \) and \( A \gtrsim B \).
Lemma 1. Let $u_I \in U_h$ be the Lagrange interpolation of $u$, satisfying $u_I(\nu) = u(\nu)$, $\forall \nu \in V$. Then, under the two geometric assumptions (G2) and (G3), we have the following interpolation error estimates

$$\|u - u_I\|_{m,K} \lesssim h^{2-m}\|u\|_{2,K}, \quad m = 0, 1, 2, \forall u \in H^2(K).$$

Proof. If $m = 0, 1$ (resp. $m = 2$), then the proof of (11) can be found in Theorem 1 and Corollary 1 in [13] (resp. Theorem 1 in [42]). □

Lemma 2. Assume that $T_h$ is a conforming mesh, which consists of general convex polygons, and satisfies the same geometric assumptions of Lemma 1. Let $u$ be the exact solution of (1) and (2), and $u_h$ the polygonal finite element solution of (9). Then, if $u \in H^2(\Omega)$, we have the following optimal $L^2$ and $H^1$ error estimates

$$\|u - u_h\|_m \lesssim h^{2-m}\|u\|_2, \quad m = 0, 1.$$

Proof. By using Lemma 1 and the similar discussions (e.g. Aubin-Nitsche technique) for the classical continuous Galerkin finite element method of Lagrange type on triangular or quadrilateral meshes (e.g. [2, 3]), we reach (12). □

3. A finite volume element solution based on postprocessing technique

3.1. The dual mesh. For any $K \in M$, suppose that $x_K$ is an arbitrary interior point of $K$ and $x_i$ is the midpoint of line segment $\nu_i\nu_{i+1}$ ($i = 1, \ldots, n$). Connecting the cell center with the edge midpoints, we obtain a subdivision of $K$, consisting of $n$ quadrilaterals. For each vertex $\nu \in V$, the dual cell associated with $\nu$ is a polygonal domain surrounding $\nu$ and denoted as $D^*_\nu$. Precisely, if $\nu = \nu_i$ is the $i$-th vertex of $K$, then the contribution of $K$ to $D^*_\nu$ is the quadrilateral $\nu_i x_i x_K x_{i-1}$. The dual cell associated with the interior vertex $\nu_i$ is shown in Figure 2 for an example.

The dual mesh $T_h^*$ consists of all dual cells, given by

$$T_h^* = \{D^*_\nu : \nu \in V\},$$

and the corresponding test function space for FVEM is defined by

$$V_h = \text{Span}\{\psi_\nu : \nu \in V^\text{int}\},$$

where $\psi_\nu$ is the characteristic function on $D^*_\nu$, i.e., $\psi_\nu(x) = 1$ if $x \in D^*_\nu$, $\psi_\nu(x) = 0$ if $x \notin D^*_\nu$. Moreover, let $\Pi$ be a linear mapping which maps $u_h \in U_h$ to $u^*_h := \Pi u_h \in V_h$, and satisfies

$$u^*_h(\nu) = u_h(\nu), \forall \nu \in V^\text{int}.$$
If $u_h$ is the polygonal finite element solution of (9), then in general, it does not satisfy the following local conservation property
\begin{equation}
\int_{\partial D^*_\nu} (\Lambda \nabla u_h) \cdot \mathbf{n} \, ds + \int_{D^*_\nu} f \, dx \, dy = 0
\end{equation}
for any $\nu \in V^{\text{int}}$, where $\mathbf{n}$ denotes the unit normal vector outward to $\partial D^*_\nu$. For example, on triangular meshes, the polygonal finite element solution is identical to the standard $P_1$ finite element solution since the uniqueness of generalized barycentric coordinates. As a result, $u_h$ doesn’t satisfy the local conservation property, even though $n = 3$.

However, for the finite volume element solution, it preserves the property (14) on a certain dual mesh (e.g. [18, 20, 37, 42]). In this paper, we postprocess the polygonal finite element solution $u_h$ of (9) to generate a new continuous function $b_u h$, such that the new polygonal finite volume element solution satisfies the local conservation property on the dual mesh $T'_h$, and preserves the optimal $H^1$ and $L^2$ error estimates on the primary mesh $T_h$. For this purpose, a general construction of new $n$ bubble functions for each cell $K$ and a postprocessing algorithm are presented as follows.

3.2. The postprocessing technique. In order to introduce the postprocessing technique, we first introduce the new bubble function $\psi_j$ as below
\begin{equation}
\psi_j = \begin{cases} 
\lambda_{x_K} \lambda_{\nu_j} \lambda_{\nu_j+1}, & \text{in } \triangle x_K \nu_j \nu_{j+1}, \\
0, & \text{otherwise},
\end{cases} \quad j = 1, \cdots, n,
\end{equation}
where $\lambda_{x_K}, \lambda_{\nu_j}$ and $\lambda_{\nu_j+1}$ denote three linear nodal basis functions of the triangle $x_K \nu_j \nu_{j+1}$. We plot the contours of six bubble functions for the case $n = 6$ in Figure 3. Moreover, in each $K \in \mathcal{M}$, for the polygonal finite element solution $u_h$ of (9), we define the following trilinear form
\begin{equation}
R_K(f, u_h, v_h) = \int_K f(v_h^* - u_h) \, dx \, dy + \int_K (\Lambda \nabla u_h) \cdot \nabla v_h \, dx \, dy + \int_{\partial K} \{\Lambda \nabla u_h\} \cdot \mathbf{n}(v_h^* - u_h) \, ds,
\end{equation}
where $v_h \in U_h$, and $v_h^* \in V_h$ is the piecewise constant function defined by (13), $\mathbf{n}$ denotes the unit normal vector outward to $\partial K$. \{\} denotes an averaging operator.
on $\partial K$, i.e., for any edge $\sigma = K_1 \cap K_2$, vectorial function $v$ satisfies
\[
\{v\}_\sigma = \frac{1}{2} (v|_{\sigma, K_1} + v|_{\sigma, K_2}).
\]

Next, we introduce the postprocessing technique. For each $K \in M$, we define the post-processed solution as
\[
\hat{u}_h = u_h + \sum_{j=1}^{n} c_j \psi_j,
\]
where $c_j$ $(j = 1, \cdots, n)$ are some coefficients to be determined. We require that $\hat{u}_h$ satisfies
\[
- \int_{(\partial D_i^*) \cap K} (\Lambda \nabla \hat{u}_h) \cdot n \, ds = R_K(f, u_h, \phi_{\nu_i}), \quad i = 1, \cdots, n,
\]
\[
\sum_{j=1}^{n} \hat{u}_h(y_j) = \sum_{j=1}^{n} u_h(y_j),
\]
where $y_j$ is the barycenter of $\Delta x_K x_{j+1}$.

**Lemma 3.** The equations in (18) have linear correlation.

**Proof.** In each cell $K$, by (7) and noticing that $\Lambda \nabla \hat{u}_h$ is smooth across each edge of $(\partial D_i^*) \cap K$ (i.e., $x_{i-1} x_K$ and $x_i x_{K'}$), then we find that
\[
\sum_{i=1}^{n} \left( R_K(f, u_h, \phi_{\nu_i}) + \int_{(\partial D_i^*) \cap K} (\Lambda \nabla \hat{u}_h) \cdot n \, ds \right) = R_K(f, u_h, 1) = 0,
\]
and complete the proof.

Lemma 3 shows that, for each $K$, the local linear algebraic system (18) has linear correlation, and the coefficient matrix of (18) is $A_K = (a_{ij})_{n \times n}$ with the entries
\[
a_{ij} = - \int_{(\partial D_i^*) \cap K} (\Lambda \nabla \psi_j) \cdot n \, ds, \quad i, j = 1, \cdots, n.
\]

Thus, for the existence and uniqueness of $\hat{u}_h$, it needs to satisfy (19) additionally. Here, we only analyze the one case, which consists in replacing the last equation in (18) with (19), and the other cases are similar. In this case, the new $n \times n$ local algebraic system is given by
\[
B_K c_K = b_K,
\]
where $c_K = (c_1, \cdots, c_n)^T$, and the entries of $B_K$ and $b_K$ are
\[
b_{ij} = a_{ij}, \quad b_{n,j} = \frac{1}{81}, \quad i = 1, \cdots, n-1, \quad j = 1, \cdots, n,
\]
\[
b_i = \text{RHS}_i, \quad b_n = 0, \quad i = 1, \cdots, n-1,
\]
\[
\text{RHS}_i = R_K(f, u_h, \phi_{\nu_i}) + \int_{(\partial D_i^*) \cap K} (\Lambda \nabla u_h) \cdot n \, ds.
\]
If $B_K$ is a nonsingular matrix, then we can obtain the existence and uniqueness of $\hat{u}_h$. In brief, we summarize the above postprocessing technique in Algorithm 1.
Algorithm 1: The FVEM based on postprocessing technique.

Step 1: Compute the polygonal finite element solution $u_h$ by (9);
Step 2: Do $K \in M$
  Solve the local linear algebraic system (21) on the cell $K$ to get the coefficients $c_j (j = 1, \cdots, n)$ of (17);
  Enddo
Step 3: Obtain the post-processed solution $\tilde{u}_h$ by (17).

4. Local conservation, existence and uniqueness

Theorem 1. For the post-processed solution $\tilde{u}_h$ defined by (17)-(19), it satisfies the following local conservation property

$$-\int_{\partial D_{\nu}} (\Lambda \nabla \tilde{u}_h) \cdot \mathbf{n} \, ds = \int_{D_{\nu}} f \, dx \, dy, \quad \forall \nu \in V^{int}.$$  

Proof. Assume that $\omega_{\nu} = \bigcup \{K_i : \nu \in K_i, K_i \in M\}$, then for each $\nu \in V^{int}$, we deduce from (18), (16) and (9) that

$$-\sum_{K \in \omega_{\nu}} \int_{(\partial D_{\nu}) \cap K} (\Lambda \nabla \psi_i) \cdot \mathbf{n} \, ds = \sum_{K \in \omega_{\nu}} R_K(f, u_h, \phi_{\nu})$$

$$= \sum_{K \in \omega_{\nu}} \left( \int_{K} f (\phi_{\nu}^* - \phi_{\nu}) \, dx \, dy + \int_{K} (\Lambda \nabla u_h) \cdot \nabla \phi_{\nu} \, dx \, dy \right)$$

$$= \int_{D_{\nu}} f \, dx \, dy + [a(u_h, \phi_{\nu}) - (f, \phi_{\nu})]$$

$$= \int_{D_{\nu}} f \, dx \, dy.$$

Noticing

$$-\int_{\partial D_{\nu}} (\Lambda \nabla \tilde{u}_h) \cdot \mathbf{n} \, ds = -\sum_{K \in \omega_{\nu}} \int_{(\partial D_{\nu}) \cap K} (\Lambda \nabla \psi_i) \cdot \mathbf{n} \, ds,$$

and then the desired result (24) is verified. 

Lemma 4. Assume that the diffusion tensor $\Lambda$ is constant on $K$. Then, for any $x_K \in K$, we have

$$a_{ii} = \frac{1}{96 A_i(x_K)} (x_i - x_K)^T R^T \Lambda R (x_i - x_K), \quad i = 1, \cdots, n,$$

where $x_i$ is the midpoint of line segment $\nu_i \nu_{i+1}$, see Figure 2, and $A_i(x)$ is defined by (4). Furthermore, under the assumption (3), we have

$$a_{ii} > 0, \quad i = 1, \cdots, n.$$

Proof. From (20) and (15), we have

$$a_{ii} = -\int_{x_i - x_K} (\Lambda \nabla \psi_i) \cdot \mathbf{n} \, ds,$$

where $\mathbf{n} = -R(x_i - x_K)/|x_i - x_K|$. By direct calculations,

$$\nabla \psi_i(x_K) + 4 \nabla \psi_i \left( \frac{x_K + x_i}{2} \right) + \nabla \psi_i(x_i) = \frac{1}{16 A_i(x_K)} R(x_i - x_K).$$
Since the integrand of (27) is a cubic function, by the Simpson’s rule, one reaches (25). Recalling that \( A_i(x_K) > 0 \) and \( x_i \neq x_K \), then (26) is a direct consequence of (3) and (25).

\[ \text{Theorem 2. Suppose that the diffusion tensor } \Lambda \text{ is constant on any cell in } \mathcal{M}. \text{ Then, there exists a unique } u_h, \text{ satisfying (17), (18) and (19) simultaneously.} \]

**Proof.** What we need is to prove that the matrix \( \mathbb{B}_K \) in (21) is nonsingular. Let \( a_{n+1,n} = a_{1,n} \). Then, from (20) and (15), we have

\[ a_{ii} + a_{i+1,i} = 0, \quad i = 1, \cdots, n \]

and

\[ a_{ij} = 0, \quad j \neq i - 1, i. \]

It follows from (22) that

\[ \det(\mathbb{B}_K) = \frac{1}{81} \prod_{i=1}^{n} a_{ii} \sum_{i=1}^{n} \frac{1}{a_{ii}}, \]

which implies the nonsingularity of \( \mathbb{B}_K \) and verifies the result of this theorem by Lemma 4.

\[ \text{5. Error estimates} \]

To begin with, we introduce the following geometric assumption.

- **(G6)** There exists a positive constant \( r_\ast \), independent of \( h \), such that

\[ d_{K,i} > r_\ast h_K, \quad i = 1, \cdots, n, \quad \forall K \in \mathcal{M}, \]

where \( d_{K,i} \) denotes the distance from the cell center \( x_K \) to the edge \( \nu_i \nu_{i+1} \).

\[ \text{Proposition 4. Under the geometric assumption (G1), there exists at least one point } x_K \in K \text{ satisfying the geometric assumption (G6).} \]
Proof. For example, let \( x_K \) be the center of the largest circle inscribed in \( K \). From (G1), we find that
\[
d_{K,i} \geq \rho_K > \frac{1}{\gamma^*} h_K,
\]
which leads to (G6) with \( r_* = 1/\gamma^* \). The proof is complete. \(\square\)

Lemma 5. Suppose that the diffusion tensor \( \Lambda \) is piecewise constant with respect to the primary mesh, or alternatively, piecewise \( W_1^\infty \) and the mesh size \( h \) is small enough. Then, under the assumptions (3), (G2) and (G6), we have
\[
\det (B_K) \sim 1, \quad \forall K \in \mathcal{M}.
\]
Proof. Firstly, we prove the case when \( \Lambda \) is piecewise constant with respect to the primary mesh. From (G2) and (G6), we have
\[
\frac{1}{2} h_K^2 > A_1(x_K) = \frac{1}{2} d_{K,i} ||\nu_i - \nu_{i+1}|| > \frac{1}{2} r_* d_* h_K^2,
\]
\[
h_K > ||x_i - x_K|| \geq d_{K,i} > r_* h_K.
\]
It follows from (25) and (3) that
\[
\frac{\lambda^2}{48} < \frac{\Lambda ||x_i - x_K||^2}{96 A_1(x_K)} \leq a_{ii} \leq \frac{\Lambda ||x_i - x_K||^2}{96 A_1(x_K)} < \frac{\lambda}{48 r_* d_*}, \quad i = 1, \ldots, n.
\]
Recall that (G2) implies (G5). Hence, combining the above estimate with (30) leads to (31).

Secondly, we consider the general case where \( \Lambda \) is piecewise \( W_1^\infty \) with respect to the primary mesh. Let
\[
\Lambda|_K = \Lambda(x_K), \quad \forall K \in \mathcal{M}.
\]
By replacing \( \Lambda \) with \( \overline{\Lambda} \) in (20), we get the matrix \( \overline{B}_K = (\overline{b}_{ij})_{n \times n} \) in a way similar to that of \( \overline{B}_K \). Similar to the above arguments, we find that (31) also holds for \( \overline{B}_K \).

According to (15), we know \( ||\nabla \psi_j|| \lesssim h_K^{-1}, \forall x \in (\partial D^*_\nu) \cap K \), where we have used the facts that in \( \Delta x_K \nu_j \nu_{j+1} \]
\[
|\lambda_{\nu}| \lesssim 1, \quad ||\nabla \lambda_{\nu}|| \lesssim h_K^{-1},
\]
and \( \lambda_{\nu} \) is any linear nodal basis function. Then we have \( |b_{ij} - \overline{b}_{ij}| \lesssim h \) and
\[
|\det (B_K) - \det (\overline{B}_K)| \lesssim h.
\]
Therefore, when the mesh size \( h \) is sufficiently small, one can still reach (31). The proof is complete. \(\square\)

Lemma 6. Under the assumptions (G2) and (G3), for any \( K \in \mathcal{M} \) with \( h_K = 1 \), we have
\[
\|u_h\|_{0,K} \sim \|u_h\|_{0,K,h}, \quad \forall u_h \in U_h,
\]
where the discrete norm
\[
\|u_h\|^2_{0,K,h} = \sum_{i=1}^n u_i^2, \quad u_i = u_h(\nu_i).
\]
A triangle $4264$.

**Proof.** On the one hand, we have

$$\|u_h\|_{0,K} \leq \sum_{i=1}^{n} |u_i| \|\phi_i\|_{0,K} < \sum_{i=1}^{n} |u_i| \leq \sqrt{n} \left( \sum_{i=1}^{n} u_i^2 \right)^{\frac{1}{2}} \lesssim \|u_h\|_{0,K,h}.$$  

On the other hand, we denote $|u_{i_0}| = \max_{1 \leq i \leq n} |u_i|$, and we first consider the case $n \geq 4$. Set $d_* = \min\{d_*, 1/2\}$ and

$$r_0 = \frac{d_*^{4n-4} \beta 2n^2 - 2}{2n^3} < \frac{1}{10}, \quad \beta = \min\{\sin \alpha^*, \sin \alpha_*\}.$$  

We define two points $x_1$ and $x_2$ which belong to the line segments $\nu_{i_0}, \nu_{i_0-1}$ and $\nu_{i_0}, \nu_{i_0+1}$ (see Figure 4), satisfying

$$\frac{|\nu_{i_0} x_1|}{|\nu_{i_0} \nu_{i_0-1}|} = \frac{|\nu_{i_0} x_2|}{|\nu_{i_0} \nu_{i_0+1}|} = r_0,$$

and denote $K_{i_0} := \triangle x_1 \nu_{i_0} x_2$. By Lemma 2 of [42], we have

$$A_i(\nu_j) \geq \frac{1}{2} d_*^4 \beta^2, \quad \forall j \neq i, i + 1.$$  

As a result, for any $i \notin \{i_0 - 2, i_0 - 1, i_0, i_0 + 1\}$

$$A_i(x) \geq \min\{A_i(\nu_{i_0-1}), A_i(\nu_{i_0}), A_i(\nu_{i_0+1})\} \geq \frac{1}{2} d_*^4 \beta^2, \quad \forall x \in K_{i_0}.$$  

Moreover,

$$A_{i_0-2}(x) \geq \min\{A_{i_0-2}(x_1), A_{i_0-2}(\nu_{i_0}), A_{i_0-2}(\nu_{i_0+1})\} \geq \min\left\{ \frac{1}{2} d_*^4 \beta (1-r_0), \frac{1}{2} d_*^4 \beta^2 \right\} = \frac{1}{2} d_*^4 \beta^2, \quad \forall x \in K_{i_0},$$

where the fact $1 - r_0 > d_*^2 \beta$ is used. Similarly, we have $A_{i_0+1}(x) \geq d_*^4 \beta^2/2$, $\forall x \in K_{i_0}$, and

$$\max\{A_{i_0-1}(x), A_{i_0}(x)\} \leq \frac{1}{2} r_0, \quad \forall x \in K_{i_0}.$$  

Then, for any $x \in K_{i_0}$, we have

$$w_i(x) \begin{cases} \geq \frac{1}{2n-1} d_*^{4n-4} \beta 2n^2 - 2, & i = i_0, \\ \leq \frac{r_0}{2n-1}, & i = i_0 - 1, i_0 + 1, \\ \leq \frac{r_*^2}{2n-1} < \frac{r_0}{2n-1}, & i \neq i_0 - 1, i_0, i_0 + 1. \end{cases}$$
It follows that
\[
\left| \sum_{i=1}^{n} u_i w_i(x) \right| \geq |u_{i_0}| w_{i_0}(x) - \sum_{1 \leq i \leq n, i \neq i_0} |u_i| w_i(x)
\]
\[
\geq |u_{i_0}| \left( w_{i_0}(x) - \sum_{1 \leq i \leq n, i \neq i_0} w_i(x) \right)
\]
\[
\geq \frac{1}{2^n} d_s^{4n^*-4\beta^2 n^*-2} |u_{i_0}|, \quad \forall x \in K_{i_0}.
\]
Due to \( \sum_{i=1}^{n} w_i(x) < n/2^{n-1} \leq 1/2, \forall x \in K \), we have
\[
\| u_h \|_{0,K} \geq \| u_h \|_{0,K_{i_0}} \geq 2 \left\| \sum_{i=1}^{n} u_i w_i(x) \right\|_{0,K_{i_0}} \geq \frac{d_s^{4n^*-4\beta^2 n^*-2}}{2^{n-1}} |u_{i_0}||K_{i_0}|^{1/2}
\]
\[
\geq \frac{d_s^{4n^*-7\beta^2 n^*-7/2}}{2^{n+1/2} n^*} |u_{i_0}| \geq \frac{d_s^{4n^*-7\beta^2 n^*-7/2}}{2^{n+1/2} (n^*)^{3/2}} \| u_h \|_{0,K,h},
\]
where \( |K_{i_0}| \) denotes the area of \( K_{i_0} \). For the case \( n = 3 \), the Wachspress shape functions reduce to the classical linear nodal basis functions, and the proof of above inequality is trivial. Thus, we reach (32) for any \( n \geq 3 \).

Lemma 7. Under the assumptions (G2) and (G3), for any \( K \in M \), we have
\[
|u_h|_{2,K} \lesssim \frac{h_K^{-1}}{K} |u_h|_{1,K}, \quad \forall u_h \in U_h.
\]

Proof. By the following scaling transformation
\[
\mathcal{J}_K(x) := \bar{x} = \frac{x - x_K}{h_K},
\]
we can map the cell \( K \) to \( \bar{K} \) with \( h_{\bar{K}} = 1 \). According to the facts \( |\phi_i|_{1,K} \lesssim 1 \) (see Lemma 6 of [13]) and \( |\phi_i|_{2,K} \lesssim h_K^{-1} \) (see Lemma 4 of [42]), we deduce that
\[
\| u_h \|_{2,\bar{K}} \lesssim \sum_{i=1}^{n} |u_i| \| \phi_i \|_{2,\bar{K}} \lesssim \sum_{i=1}^{n} |u_i| \lesssim \| u_h \|_{0,\bar{K},h} \lesssim \| u_h \|_{0,\bar{K}},
\]
where we have used the fact (32) in the last inequality. Let
\[
\bar{u}_h = \frac{1}{|K|} \int_{K} u_h \, dx dy,
\]
it follows that
\[
|u_h|_{2,\bar{K}} = |u_h - \bar{u}_h|_{2,\bar{K}} \lesssim \| u_h - \bar{u}_h \|_{2,\bar{K}} \lesssim \| u_h - \bar{u}_h \|_{0,\bar{K}} \lesssim |u_h|_{1,\bar{K}},
\]
where in the last inequality we used the fact (1.11) of [2]. Finally, we obtain
\[
|u_h|_{2,K} = h_K^{-1} |u_h|_{2,K} \lesssim h_K^{-1} |u_h|_{1,K} = h_K^{-1} |u_h|_{1,K},
\]
and complete the proof.

Theorem 3. Suppose that \( \bar{T}_h \) is an arbitrary convex polygonal mesh. Let \( \Lambda \) be subjected to the same assumptions in Lemma 5, and \( u \) be the exact solution of (1) and (2). Then, under the assumptions (3), (G2), (G3) and (G6), for the post-processed solution \( \tilde{u}_h \) defined by (17)-(19), we have
\[
|u - \tilde{u}_h|_m \lesssim h^{2-m} \| u \|_2, \quad m = 0, 1.
\]
Proof. By recalling (12), in order to prove (34), we only need to prove
\[(35) \quad \| \hat{u}_h - u_h \|_m \lesssim h^{2-m} \| u \|_2, \quad m = 0, 1.\]
Note that in each \( K \in \mathcal{M} \), we have
\[\hat{u}_h - u_h = \sum_{j=1}^n c_j \psi_j.\]
Moreover, by (28), (29) and Lemma 5, there holds \( |a_{ij}| \lesssim 1 \), \( i, j = 1, \ldots, n \). Then, from (21) and (31),
\[|c_j| \lesssim \max_{1 \leq i \leq n} |RHS_i|, \quad j = 1, \ldots, n.\]
By (1) and the Green’s formula, for any \( i = 1, \ldots, n \), we have
\[\int_K f \phi_{u_i} \, dx dy = \int_{\mathcal{D}_h \cap K} f \, dx dy - \int_{\mathcal{D}_h \cap K} \nabla \cdot (\Lambda \nabla u) \, dx dy = -\int_{\partial(\mathcal{D}_h \cap K)} (\Lambda \nabla u) \cdot n \, ds\]
and
\[\int_K f \phi_{u_i} \, dx dy = -\int_K \nabla \cdot (\Lambda \nabla u) \phi_{u_i} \, dx dy + \int_{\partial K} \nabla \phi_{u_i} \cdot (\Lambda \nabla u) \, ds - \int_{\partial K} (\Lambda \nabla u) \cdot n \phi_{u_i} \, ds.\]
According to (16) and (23),
\[RHS_i = \int_K f(\phi_{u_i}^* - \phi_{u_i}) \, dx dy + \int_K (\Lambda \nabla u_h) \cdot \nabla \phi_{u_i} \, dx dy + \int_{\partial K} \{\Lambda \nabla u_h\} \cdot n(\phi_{u_i}^* - \phi_{u_i}) \, ds + \int_{(\partial\mathcal{D}_h) \cap K} (\Lambda \nabla u_h) \cdot n \, ds = E_1 + E_2 + E_3 + E_4,\]
where
\[E_1 = \int_K (\Lambda \nabla (u_h - u)) \cdot \nabla \phi_{u_i} \, dx dy, \quad E_2 = \int_{(\partial\mathcal{D}_h) \cap K} (\Lambda \nabla (u_h - u)) \cdot n \, ds,\]
\[E_3 = \int_{\mathcal{D}_h \cap \partial K} \{\Lambda \nabla u_h\} - \Lambda \nabla u \cdot n \, ds, \quad E_4 = \int_{\partial K} (\Lambda \nabla u - \{\Lambda \nabla u_h\}) \cdot n \phi_{u_i} \, ds.\]
It follows from the Cauchy-Schwartz inequality and trace inequality that
\[|E_1| \lesssim |u - u_h|_{1,K} |\phi_{u_i}|_{1,K} \lesssim |u - u_h|_{1,K}, \quad |E_2| \lesssim |u - u_h|_{1,K} + h_K |u - u_h|_{2,K},\]
where we have used the fact \( |\phi_{u_i}|_{1,K} \lesssim 1 \) (see Lemma 2 of [13]). By the same arguments,
\[|E_3| + |E_4| \lesssim \int_{\partial K} \{\Lambda \nabla u_h\} - \Lambda \nabla u \cdot ds \lesssim |u - u_h|_{1,\omega_K} + h_K |u - u_h|_{2,\omega_K},\]
where \( \omega_K = \{K\} \cup \{L : L \text{ and } K \text{ have one common edge}\} \). Therefore,
\[|RHS_i| \lesssim |u - u_h|_{1,\omega_K} + h_K |u - u_h|_{2,\omega_K}, \quad i = 1, \ldots, n.\]
From the triangle inequality, (11) and (33)
\[|u - u_h|_{2,K} \leq |u - u_f|_{2,K} + |u_f - u_h|_{2,K} \lesssim |u|_{2,K} + h_K^{-1} |u_f - u_h|_{1,K} \lesssim |u|_{2,K} + h_K^{-1} |u - u_h|_{1,K}.\]
By recalling (15), the bubble function $\psi_j$ is a polynomial in $\Delta x_K \nu_i \nu_{i+1}$ and vanishes outside of this triangle, then we have

$$\|\psi_j\|_{m,K} \lesssim h_K^{1-m}, \quad m = 0, 1.$$ 

It follows that

$$\|\tilde{u}_h - u_h\|_{m,K} \leq \sum_{j=1}^n |c_j| \|\psi_j\|_{m,K} \lesssim h_K^{1-m} \max_{1 \leq j \leq n} |c_j| \lesssim h_K^{1-m} \max_{1 \leq i \leq n} |RHS_i|$$

$$\lesssim h_K^{1-m} |u - u_h|_{1,\omega_K} + h_K^{2-m} \|u\|_{2,\omega_K}, \quad m = 0, 1.$$ 

Note that (12), then (35) is obtained by summing up the above inequality over all polygonal cells. The proof is complete.

**Remark 1.** We mention that in our numerical analysis, some bubble functions cannot be chosen. For instance, in Lemma 4, if $\psi_i = \lambda_{x_K}^m \nu_i \lambda_{\nu_{i+1}}$ ($m \geq 1$), then we find that $a_{ii} = 0$. In other words, we cannot choose $\lambda_{x_K}^m \nu_i \lambda_{\nu_{i+1}}$ in (15). However, similar to the previous discussions, instead of (15), one can choose $\psi_j = \lambda_{x_K}^m \nu_j \lambda_{\nu_{j+1}}^2$. For this special case (i.e. $a_{ii} < 0$), the existence, uniqueness and optimal error estimates of the new polygonal finite volume element solution can be verified by the same arguments.

**6. Numerical experiments**

In this section, we present two numerical examples to verify the theoretical findings, where the first (resp. second) one is designed for continuous (resp. discontinuous) diffusion tensor. In our numerical experiments, we choose the square domain $\Omega = [0, 1]^2$, and employ four types of meshes, see Figures 5-8. Moreover, the following $L^2$ error $E_u$, $H^1$ error $E_q$ and local conservation error $E_c$ are used to measure the errors of new polygonal finite volume element solution $\tilde{u}_h$

$$E_u = \|u - \tilde{u}_h\|_0, \quad E_q = \|\nabla (u - \tilde{u}_h)\|_0,$$

$$E_c(\tilde{u}_h) = \max_{\nu \in V^{int}} \left| \int_{\partial D^u_\nu} (\Lambda \nabla \tilde{u}_h) \cdot \mathbf{n} \, ds + \int_{D^u_\nu} f \, dx dy \right|.$$

![Figure 5. Mesh 1: Triangular mesh.](image-url)
6.1. Example 1. We consider the anisotropic diffusion equation with the diffusion tensor and exact solution as follows

\[ \Lambda = \begin{pmatrix} 1.0 & 0.2 \\ 0.2 & 0.5 \end{pmatrix}, \quad u(x, y) = e^{-0.1x+0.2y}, \]

where the source term and Dirichlet boundary condition are chosen to match the exact solution. Table 1 shows the $H^1$ and $L^2$ errors of the new finite volume element solution $\tilde{u}_h$ on polygonal meshes, the convergence orders are 1 and 2 respectively, which validates the theoretical results in Theorem 3. More importantly, the local conservation errors for the finite element (FE) solution (blue lines, $E_c(u_h)$) and new finite volume element (FVE) solution (red lines, $E_c(\tilde{u}_h)$) are plotted in Figure 9,
Table 1. The numerical results for Example 1.

and the latter one is almost machine precision. In other words, the post-processed solution satisfies the local conservation law on the dual mesh, which confirms the findings in Theorem 1.

6.2. Example 2. In this example, the discontinuous diffusion tensor and exact solution are given by

$$
\Lambda = \begin{cases}
\Lambda_1, & x \leq 0.5, \\
\Lambda_2, & x > 0.5,
\end{cases}
\quad \Lambda_1 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},
\quad \Lambda_2 = \begin{pmatrix} 10 & 3 \\ 3 & 1 \end{pmatrix},
$$

$$
u(x,y) = \begin{cases}
-2y^2 + 4xy + 6x + 2y + 1, & x \leq 0.5, \\
-2y^2 + 1.6xy - 0.6x + 3.2y + 4.3, & x > 0.5.
\end{cases}$$

The numerical results are given in Table 2, one can observe that the performance is similar to the previous example.
7. Conclusions

In this article, we provided a new finite volume element solution for solving the anisotropic diffusion problem on arbitrary convex polygonal meshes. The new solution is obtained by postprocessing the finite element solution of the prescribed diffusion equation, where the shape function of finite element space is constructed by Wachspress generalized barycentric coordinate. Precisely, by adding some special designed element-wise bubble functions to the finite element solution, the existence and uniqueness of the new solution are verified on arbitrary convex polygonal meshes. Moreover, we proved that the new finite volume element solution satisfies the local conservation property on a certain dual mesh, and preserves the optimal $H^1$ and $L^2$ error estimates on the primary mesh.

Acknowledgments

The authors thank the reviewers for the carefully readings and providing some insightful comments and suggestions. This work was partially supported by the Guangdong Basic and Applied Basic Research Foundation (Nos. 2022A1515012106, 2023A1515010885), the project of Guangdong Polytechnic Normal University (No. 2022SDKYA023) and the scientific research capacity improvement project of the doctoral program construction unit of Guangdong Polytechnic Normal University in 2022 (No. 22GPNUZDJS31).
Table 2. The numerical results for Example 2.
